项目实战

Tornado 实战项目(伪 JD 商城)

预备知识

在之前 tornado 商城项目中,在开始之前需要引入一些项目设计知识,如接口,抽象方法抽象类,组合,程序设计原则等,个人理解项目的合理设计可增加其灵活性, 降低数据之间的耦合性,提高稳定性,下面介绍一些预备知识

1、接口

其实 py 中没有接口这个概念。要想实现接口的功能,可以通过主动抛出异常来实现

接口作用:对派生类起到限制的作用

```
#!/usr/bin/env python
# -*- coding: utf-8 -*-
接口, python 中的接口, 通过在父类中主动抛出异常实现
接口的作用:起到了限制的作用
class IFoo:
      def funl(self):
            pass
            raise Exception("错误提示")
class Bar(IFoo):
      def fun1(self):
            #方法名必须和父类中的方法名相同,不然没办法正常执行,会抛出异常
            print("子类中如果想要调用父类中的方法,子类中必须要有父类中的方法名")
      def fun2(self):
            print("test")
obi = Bar()
ob j. fun2()
```

2.抽象方法抽象类

抽象类,抽象方法是普通类和接口的综合,即可以继承也可以起到限制作用 由于 python 本身没有抽象类、接口的概念,所以要实现这种功能得 abc.py 这个类库, 具体实现方法如下:

```
#!/usr/bin/env python
# -*- coding: utf-8 -*-
抽象类,抽象方法
抽象类,抽象方法是普通类和接口的综合,即可以继承也可以起到限制作用
import abc
class Foo(metaclass=abc.ABCMeta):
      def fun1(self):
             print("fun1")
      def fun2(self):
             print("fun2")
      @abc.abstractclassmethod
      def fun3(self):
             pass
class Bar (Foo):
      def fun3(self):
             print("子类必须有父类的抽象方法名,不然会抛出异常")
obj = Bar()
obj.fun1()
obj.fun2()
```

```
obj.fun3()
```

3.组合

python 中"多用组合少用继承",因为继承的偶合性太强,可以把基类,当做参数传入派生类中,用于解偶

§继承

```
#!/usr/bin/env python
# -*- coding: utf-8 -*-
#继承
class Animals:
       def eat(self):
               print(self.Name + " eat")
        def drink(self):
               print(self.Name + " drink")
class Person(Animals):
       def init (self, name):
               self.Name = name
       def think(self):
               print(self.Name + " think")
obj = Person("user1")
obj.drink()
obj.eat()
obj. think()
```

§组合

```
class Animals:
    def __init__(self, name):
        self.Name = name

    def eat(self):
        print(self.Name + "eat")
```

4.依赖注入

像上一例中,如果有多层关系时,需要传入多个对象,为了解决这个问题就引入了依赖注入,如上例在 Person 类实例化时自动传入 **Animals 对象**

```
class Foo:
    def __init__(self):
        self.name = 111

    def fun(self)
        print(self.name)

obj = Foo() #obj是Foo的实例化对象
```

在 python 中一切皆对象,Foo 是通过 type 类创建的

```
#!/usr/bin/env python
# -*- coding:utf-8 -*-
class MyType(type):
       def call (cls, *args, **kwargs):
              obj = cls. new (cls, *args, **kwargs)
              obj. init (*args, **kwargs)
              return obj
class Foo(metaclass=MyType):
       def init (self, name):
              self.name = name
       def f1(self):
              print(self.name)
解释器解释:
     1. 遇到 class Foo, 执行 type 的 init 方法
     1. Type 的 init 的方法里做什么么呢? 不知道
            obj = Foo(123)
     3. 执行 Type 的 call 方法
            执行 Foo 类的 __new__方法
            执行 Foo 类的 init 方法
```

new 和 __init()和__metaclass__:

- ___new___函数是实例一个类所要调用的函数,每当我们调用 obj = Foo()来实例一个类时,都是先调用___new___()
- 然后再调用__init__()函数初始化实例. __init__()在__new__()执行后执行,
- 类中还有一个属性 __metaclass___,其用来表示该类由 谁 来实例化创建,所以,我们可以为 __metaclass___ 设置一个 type 类的派生类,从而查看 类 创建的过程。

那么依赖注入的实现方法,自定义一个 type 方法,实例化类的时候指定由自定义的 type 方法创建,具体实现方法如下:

```
#!/usr/bin/env python
# -*- coding: utf-8 -*-
# 依赖注入应用
#DI
class Mapper:
       __mapper_relation = {}
       @staticmethod
       def register(cls, value):
               Mapper. mapper relation[cls] = value
       @staticmethod
       def exist(cls):
               if cls in Mapper. mapper relation:
                       return True
               return False
       @staticmethod
       def value(cls):
               return Mapper. mapper relation[cls]
class MyType(type):
       def call (self, *args, **kwargs):
               obj = self.__new__(self, *args, **kwargs)
               arg list = list(args)
               if Mapper.exist(self):
                       value=Mapper. value (self)
                       arg list.append(value)
               obj. init (*arg list, **kwargs)
               return obj
```

```
#定义由谁来实例化
class Foo(metaclass=MyType):
       def init (self, name):
               self.name = name
       def f1(self):
               print(self.name)
class Bar(metaclass=MyType):
       def init (self, name):
               self.name = name
       def f1(self):
               print(self.name)
Mapper. register (Foo, "test1")
Mapper. register (Bar, "test12")
f=Foo()
print(f.name)
```

5.程序的设计原则

1. 单一责任原则(SRP)

一个对象只对一个元素负责

优点;

消除耦合,减小因需求变化引起代码僵化

2.开放封闭原则(OCP)

例如装饰器,可以对独立的功能实现扩展,但对源码不能进行修改 对扩展开放,对修改封闭

优点:

按照 OCP 原则设计出来的系统,降低了程序各部分之间的耦合性,其适应性、灵活性、稳定性都比较好。当已有软件系统需要增加新的功能时,

不需要对作为系统基础的抽象层进行修改,只需要在原有基础上附加新的模块就能实现所需要添加的功能。 增加的新模块对原有的模块完全没有影响或影响很小,

这样就无须为原有模块进行重新测试

如何实现?

在面向对象设计中,不允许更必的是系统的抽象层,面允许扩展的是系统的实现层,所以解决问题的关键是在于抽象化。

在面向对象编程中,通过抽象类及接口,规定具体类的特征作为抽象层,相对稳定,不需要做更改的从面可以满足"对修改关闭"的原则,而从抽象类导出的具体类可以

改变系统 的行为,从而满足"对扩展开放的原则"

3.里氏替换原则(LSP)

子类可以替换父类,父类出现的地方都可以用子类替换 可以使用任何派生类(子类)替换基类

优点:

可以很容易的实现同一父类下各个子类的互换,而客户端可以毫不察觉

4.接口分享原则(ISP)

对于接口进行分类避免一个接口的方法过多,避免"胖接口"

优点:

会使一个软件系统功能扩展时,修改的压力不会传到别的对象那里

如何实现?

得用委托分离接口

利用多继承分离接口

5.依赖倒置原则(DIP)

高层模块不应该依赖低层模块,二者都应该依赖其抽象(理解为接口);抽象不应该依赖细节;细节应该依赖抽象

隔离关系,使用接口或抽象类代指

高层次的模块不应该依赖于低层次的模块,而是,都应该依赖于抽象 优点:

使用传统过程化程序设计所创建的依赖关系,策略依赖于细节,这是糟糕的,因为策略受到细节改变的影

依赖倒置原则使细节和策略都依赖于抽象,抽象的稳定性决定了系统的稳定性

6.依赖注入(DI)和控制反转原则(ICO)

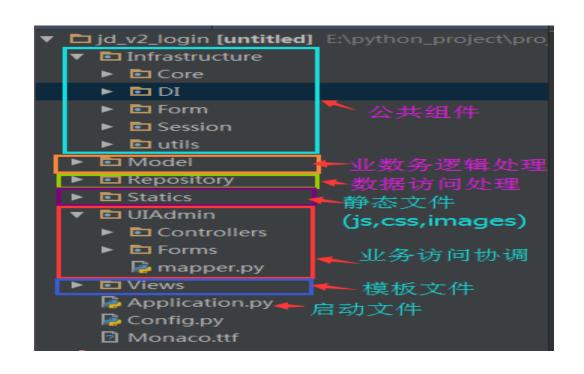

使用钩子再原来执行流程中注入其他对象

tornado 项目设计实例

实例只包含登录,写此实例目的在于更好的理解及应用以上的内容

1、目录规划

响。

Infrastructure 目录: 公共组件目录

Model:业务逻辑处理目录

Repository: 数据仓库及数据处理目录

Statics: 静态文件目录如 (css, js, images 等)

UIAdmin: UI 层

Views:模板文件目录

Application.py: 服务启动文件

2.业务访问流程

介绍完目录规划,那就来讲讲业务访问流程及数据走向

启动服务后,客户端访问 URL,根据 tornado 路由找到相对的 handler 进行处理 找到 handler 后其相对方法(get/post/delete/put)中调用 Model 逻辑处理层方法进行处理并接收处理结果 Model 逻辑处理层需

- ①创建接口
- ②建模
- ③创建协调层

创建完之后 , 由协调层 (这里通用 Services) 调用数据层方法并接收处理结果返回给 handler

- 4. 数据处理层接收到 Model 调用后,处理数据并将数据返回给 Model 业务逻辑处理层
- 5. 最终 handler 接收到最终结果,进行判断处理,并将处理结果返回给用户

3、落实实施

1.启动文件,路由关系配置

```
#!/usr/bin/env python
# -*- coding:utf-8 -*-
import tornado. ioloop
import tornado. web
from UIAdmin. Controllers import Account
from UIAdmin. Controllers import Region
from UIAdmin. Controllers import Customer
from UIAdmin. Controllers import Merchant
from UIAdmin import mapper
settings = {
    'template path': 'Views',
    'static path': 'Statics',
    'static url prefix': '/statics/',
application = tornado.web.Application([
    (r"/login", Account.LoginHandler),
    (r"/check", Account. CheckCodeHandler),
], **settings)
if name == " main ":
    application. listen (8000)
    tornado. ioloop. IOLoop. instance(). start()
```

说明:

settings 中指定配置,如模板文件路径,静态文件路径等 application:路由配置,那个路径由那个 handler 进行处理

2.handler 配置

```
#!/usr/bin/env python
# -*- coding: utf-8 -*-
import io
```

```
from Infrastructure. Core. HttpRequest import BaseRequestHandler
from Infrastructure.utils import check code
from Model. User import UserService
class LoginHandler(BaseRequestHandler):
   def get(self, *args, **kwargs):
        self.render("Admin/Account/login.html")
   def post(self, *args, **kwargs):
       username = self.get argument("username", None)
        email = self.get argument("email", None)
       pwd = self.get argument("pwd", None)
        code = self.get argument("checkcode", None)
        service = UserService()
       result = service. check login (user=username, email=email, pwd=pwd)
        #obj 封装了所有的用户信息, UserModel 对象
        if result and code.upper() == self.session["CheckCode"].upper():
            self.session['username'] = result.username
            self.redirect("/ProvinceManager.html")
        else:
            self.write("alert('error')")
```

handler中主要是针对数据访问方式的不同,给出不同的处理方法,并将结果返回给客户端

3.Model 逻辑处理层

```
逻辑处理层中,着重看的有三点:
建模
接口
协调
```

```
#!/usr/bin/env python
# -*- coding: utf-8 -*-
#建模
from Infrastructure.DI.Meta import DIMetaClass
```

```
class VipType:
   VIP TYPE = (
       {'nid': 1, 'caption': '铜牌'},
       {'nid': 2, 'caption': '银牌'},
       {'nid': 3, 'caption': '金牌'},
       {'nid': 4, 'caption': '铂金'},
   def init (self, nid):
       self.nid = nid
   def get caption(self):
       caption = None
       for item in VipType.VIP_TYPE:
           if item['nid'] == self.nid:
               caption = item['caption']
               break
       return caption
   caption = property(get_caption)
class UserType:
   USER TYPE = (
       {'nid': 1, 'caption': '用户'},
       {'nid': 2, 'caption': '商户'},
       {'nid': 3, 'caption': '管理员'},
   def init (self, nid):
       self.nid = nid
```

```
def get caption(self):
          caption = None
          for item in UserType. USER TYPE:
              if item['nid'] == self.nid:
                  caption = item['caption']
                  break
          return caption
      caption = property(get caption)
  class UserModel:
      def init (self, nid, username, password, email, last login, user type obj, vip type obj):
          self.nid = nid
          self.username = username
          self.email = email
          self.password = password
          self.last login = last login
          self.user type obj = user type obj
          self.vip type obj = vip type obj
接口 IUseRepository 类:接口类,用于约束数据库访问类的方法
  class IUserRepository:
      def fetch one by user (self, user, pwd):
          根据用户名和密码获取对象
          :param user:
          :param pwd:
          :return:
```

def fetch one by email(self, user, pwd):

```
根据邮箱和密码获取对象
:param user:
:param pwd:
:return:
```

协调 协调作用主要是调用数据处理层的方法,并将数据处理层处理后的结果返回给它的上一层的调度者

4.Repository 数据处理层

将处理后结果(usermodel对象)返回给上一层调度者(UserService)

```
#!/usr/bin/env python
# -*- coding:utf-8 -*-
#数据表创建
from sqlalchemy.ext.declarative import declarative_base
from sqlalchemy import Column
from sqlalchemy import Integer, Integer, CHAR, VARCHAR, ForeignKey, Index, DateTime, DECIMAL, TEXT
from sqlalchemy.orm import sessionmaker, relationship
from sqlalchemy import create_engine
```

```
engine = create_engine("mysql+pymysql://root:123@127.0.0.1:3306/ShoppingDb?charset=utf8", max_overflow=5)
Base = declarative base()
class Province (Base):
    省
    __tablename__ = 'province'
   nid = Column(Integer, primary key=True)
   caption = Column (VARCHAR (16), index=True)
class City(Base):
    市
    """
    __tablename__ = 'city'
   nid = Column(Integer, primary key=True)
   caption = Column (VARCHAR (16), index=True)
   province id = Column(Integer, ForeignKey('province.nid'))
class County(Base):
    县(区)
    tablename = 'county'
   nid = Column(Integer, primary key=True)
   caption = Column(VARCHAR(16), index=True)
   city id = Column(Integer, ForeignKey('city.nid'))
```

```
class UserInfo(Base):
   用户信息
   tablename = 'userinfo'
   nid = Column(Integer, primary key=True)
   USER TYPE = (
       {'nid': 1, 'caption': '用户'},
       {'nid': 2, 'caption': '商户'},
        {'nid': 3, 'caption': '管理员'},
   user type = Column(Integer)
   VIP TYPE = (
       {'nid': 1, 'caption': '铜牌'},
       {'nid': 2, 'caption': '银牌'},
       {'nid': 3, 'caption': '金牌'},
        {'nid': 4, 'caption': '铂金'},
   vip = Column(Integer)
   username = Column (VARCHAR (32))
   password = Column (VARCHAR (64))
   email = Column (VARCHAR (64))
   last_login = Column(DateTime)
   ctime = Column(DateTime)
   table args = (
       Index('ix user pwd', 'username', 'password'),
       Index('ix_email_pwd', 'email', 'password'),
```

```
#!/usr/bin/env python
  # -*- coding: utf-8 -*-
  from Model. User import IUserRepository
  from Model. User import UserModel
  from Model. User import UserType
  from Model.User import VipType
  from Repository. Admin. DbConnection import DbConnection
  class UserRepository(IUserRepository):
      def init (self):
           self.db conn = DbConnection()
      def fetch one by email(self, email, password):
          ret = None
          cursor = self.db conn.connect()
           sql = """select nid, username, password, email, last login, vip, user type from userinfo where email=%s and password=%s"""
           cursor. execute (sql, (email, password))
           db result = cursor. fetchone()
           self.db conn.close()
          print(type(db result), db result)
          if db result:
              ret = UserModel(nid=db result['nid'],
                               username=db result['username'],
                               password=db result['password'],
                               email=db result['email'],
                               last login=db result['last login'],
                               user type obj=UserType(nid=db result['user type']),
                               vip type ob j=VipType (nid=db result['vip']),)
               return ret
          return db result
```

```
def fetch_one_by_user(self, username, password):
         ret = None
         cursor = self.db conn.connect()
          sql = """ select nid, username, password, email, last login, vip, user type from userinfo where username=%s and password=%s"""
          cursor.execute(sql, (username, password))
          db result = cursor. fetchone()
          self.db conn.close()
         if db result:
      #建模,将 usermodel 对象返回给上一层调用者,因为要向用户展示的 user type 不可能为 1,2 这些数据而应该是相对的 caption
             ret = UserModel(nid=db result['nid'],
                            username=db result['username'],
                            password=db result['password'],
                            email=db result['email'],
                            last login=db result['last login'],
                            user_type_obj=UserType(nid=db_result['user_type']),
                            vip type obj=VipType(nid=db result['vip']),)
             return ret
         return db result
5.Handler 最终处理
接收到最终处理结果后判断,并返回数据给用户
说明:
   有没有注意到 UserService 是怎么和数据处理层建立联系的?
   这里我们用到了依赖注入,具体配置如下:
  #!/usr/bin/env python
  # -*- coding:utf-8 -*-
  #依赖注入
  class DIMapper:
```

mapper dict = {}

def inject (cls, arg):

@staticmethod

```
if cls not in DIMapper. mapper dict:
           DIMapper. mapper dict[cls] = arg
   @staticmethod
   def get mappers():
       return DIMapper. mapper dict
class DIMetaClass(type):
   def call (cls, *args, **kwargs):
       # 获取配置的对应的对象,携带进入
       obj = cls. new (cls, *args, **kwargs)
       mapper dict = DIMapper.get mappers()
       if cls in mapper dict:
           cls. init (obj, mapper dict[cls])
       else:
           cls.__init__(obj, *args, **kwargs)
       return obj
```

```
